

# Notes API – DevOps & Cloud-Native Project Report

## 1. Introduction

### 1.1 Project Context

This project demonstrates a complete DevOps and Cloud-Native workflow applied to a simple backend application called Notes API. The objective is not the business logic itself, but the automation, security, observability, and Kubernetes deployment around the application. The project follows industry best practices including CI/CD pipelines, GitOps deployment, monitoring, logging, security scanning, and automated testing with coverage.

### 1.2 Project Goals

The main goals of this project are to build a REST API with Node.js and Express, containerize the application using Docker, deploy the application on Kubernetes using Helm, automate deployments using Argo CD (GitOps), implement full observability with metrics and logs, secure the pipeline with SAST and DAST scans, implement automated testing with coverage reports, and provide a production-like DevOps workflow.

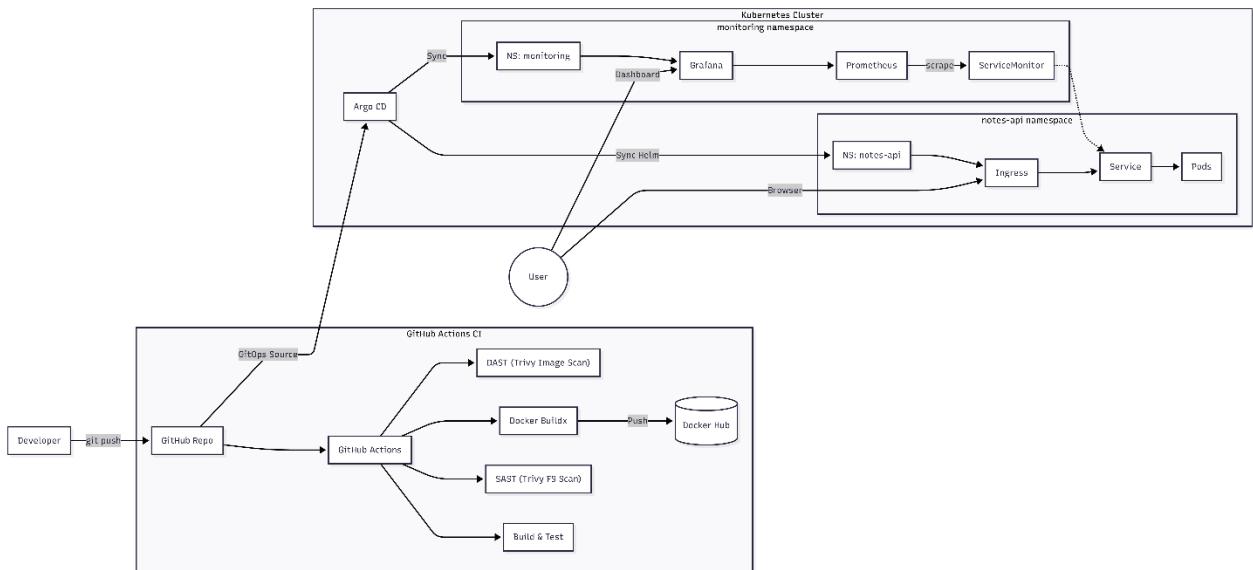

### 1.3 Technologies Used

The project utilizes Node.js and Express for the backend, Docker for containerization, Kubernetes with Minikube for orchestration, Helm for packaging, Argo CD for GitOps, GitHub Actions for CI/CD, Prometheus for monitoring, Grafana for visualization, Trivy for security scanning, Jest and Supertest for testing, prom-client for metrics, and structured JSON logs for logging.

## 2. Architecture Overview

### 2.1 High-Level Architecture

The system follows a cloud-native microservice architecture. Developers push code to GitHub, which triggers GitHub Actions CI/CD pipelines. The application is tested, scanned, built, and pushed as a Docker image. Argo CD automatically syncs the Kubernetes cluster with the desired state from Git. Kubernetes exposes the API through Ingress, while Prometheus scrapes metrics and Grafana visualizes them in dashboards.

## 2.2 Components Description

The Notes API provides RESTful CRUD operations on notes. The Docker image serves as an immutable artifact deployed across environments. The Kubernetes Deployment ensures pod lifecycle management, while Service and Ingress expose the API internally and externally. Prometheus collects application and system metrics, and Grafana displays dashboards for observability. Argo CD handles GitOps-based continuous deployment.

## 3. Kubernetes Setup

### 3.1 Cluster Creation

The Kubernetes cluster is created using Minikube, simulating a production-like environment locally.

	Name	Container ID	Image	Port(s)	CPU (%)	Last st	Actions
<input type="checkbox"/>	minikube	28b03f137f89	k8s-minikul		0%	2 days	
<input type="checkbox"/>	cool_blackburn	30937729a267	notes-api:v1	3000:3000	0%	2 mont	
<input checked="" type="checkbox"/>	notes-api	v1	0d1772bb0a2c		2 months ago	206.31 MB	
<input type="checkbox"/>	nouromry/notes-api	v1	0d1772bb0a2c		2 months ago	206.31 MB	

### 3.2 Deployments

The application is deployed using a Kubernetes Deployment managed by Helm. The deployment defines replica counts, uses resource requests and limits, includes readiness and liveness probes, and runs as a non-root container for security.

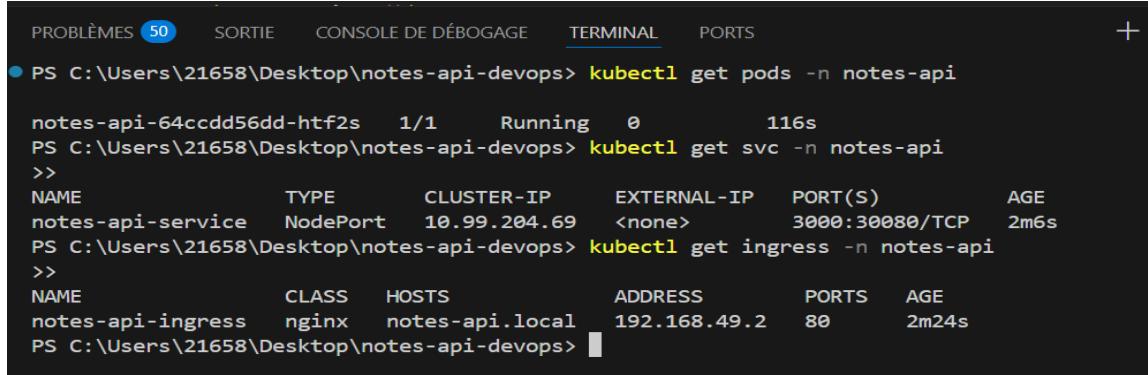

```

PROBLÈMES 50 SORTIE CONSOLE DE DÉBOGAGE TERMINAL PORTS + 
● PS C:\Users\21658\Desktop\notes-api-devops> kubectl get pods -n notes-api
notes-api-64ccdd56dd-htf2s   1/1     Running   0          116s

```

### 3.3 Services

Two services are used: a NodePort Service for external access and a ClusterIP Service for internal communication and monitoring.

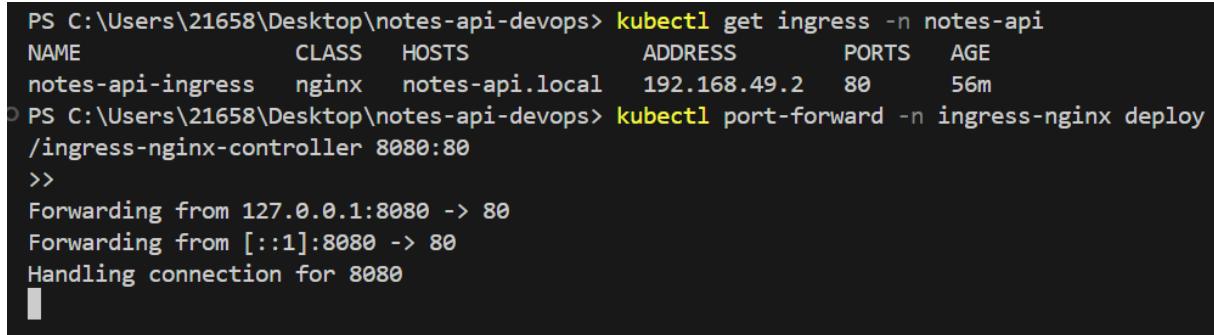

The screenshot shows a terminal window with several tabs at the top: PROBLÈMES (50), SORTIE, CONSOLE DE DÉBOGAGE, TERMINAL (which is selected), and PORTS. The terminal content displays the following commands and their outputs:

```
PS C:\Users\21658\Desktop\notes-api-devops> kubectl get pods -n notes-api
notes-api-64ccdd56dd-htf2s  1/1      Running   0          116s
PS C:\Users\21658\Desktop\notes-api-devops> kubectl get svc -n notes-api
>>
NAME           TYPE      CLUSTER-IP    EXTERNAL-IP   PORT(S)        AGE
notes-api-service  NodePort  10.99.204.69 <none>       3000:30080/TCP  2m6s
PS C:\Users\21658\Desktop\notes-api-devops> kubectl get ingress -n notes-api
>>
NAME           CLASS     HOSTS         ADDRESS        PORTS   AGE
notes-api-ingress  nginx   notes-api.local  192.168.49.2  80      2m24s
PS C:\Users\21658\Desktop\notes-api-devops>
```

### 3.4 Ingress

An NGINX Ingress Controller exposes the API via a defined hostname. The Ingress routes external traffic to the appropriate Kubernetes Service.

```
PS C:\Users\21658\Desktop\notes-api-devops> kubectl get ingress -n notes-api
NAME           CLASS     HOSTS         ADDRESS        PORTS   AGE
notes-api-ingress  nginx   notes-api.local  192.168.49.2  80      56m
PS C:\Users\21658\Desktop\notes-api-devops> kubectl port-forward -n ingress-nginx deploy /ingress-nginx-controller 8080:80
>>
Forwarding from 127.0.0.1:8080 -> 80
Forwarding from [::1]:8080 -> 80
Handling connection for 8080
|
```

### 3.5 Helm Chart Explanation

The Helm chart contains deployment, service, and ingress configuration files, along with a values.yaml for environment configuration and helper templates for reusable Helm patterns. Helm allows for easy configuration, versioning, and reuse of deployment packages.

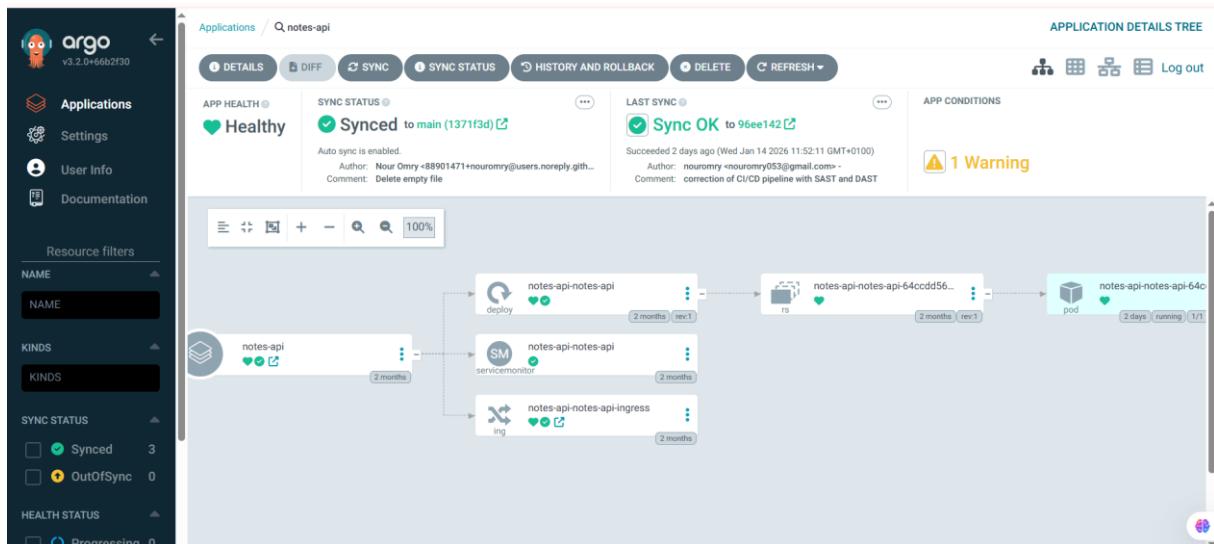

```

TEST SUITE: None
PS C:\Users\21658\Desktop\notes-api-devops> helm upgrade --install notes-
api helm/notes-api -n notes-api
>>
NAME: notes-api
LAST DEPLOYED: Fri Nov 21 22:08:05 2025
NAMESPACE: notes-api
STATUS: deployed
REVISION: 2
TEST SUITE: None
PS C:\Users\21658\Desktop\notes-api-devops> kubectl get pods -n notes-api
>> kubectl get svc -n notes-api
>> kubectl get ingress -n notes-api
NAME READY STATUS RESTARTS AGE
notes-api-64ccdd56dd-htf2s 0/1 ContainerCreating 0 23s
NAME TYPE CLUSTER-IP EXTERNAL-IP PORT(S) AGE
notes-api-service NodePort 10.99.204.69 <none> 3000:30080/TCP 23s
NAME CLASS HOSTS ADDRESS PORTS AGE
notes-api-ingress nginx notes-api.local 80 23s
PS C:\Users\21658\Desktop\notes-api-devops> minikube ip
>>
192.168.49.2

```

### 3.6 GitOps with Argo CD

Argo CD continuously monitors the GitHub repository and ensures that the Kubernetes cluster state matches the Git state. This provides benefits including declarative deployments, automatic drift correction, clear deployment history, and UI-based visibility.

## 4. Observability Stack

### 4.1 Prometheus Monitoring

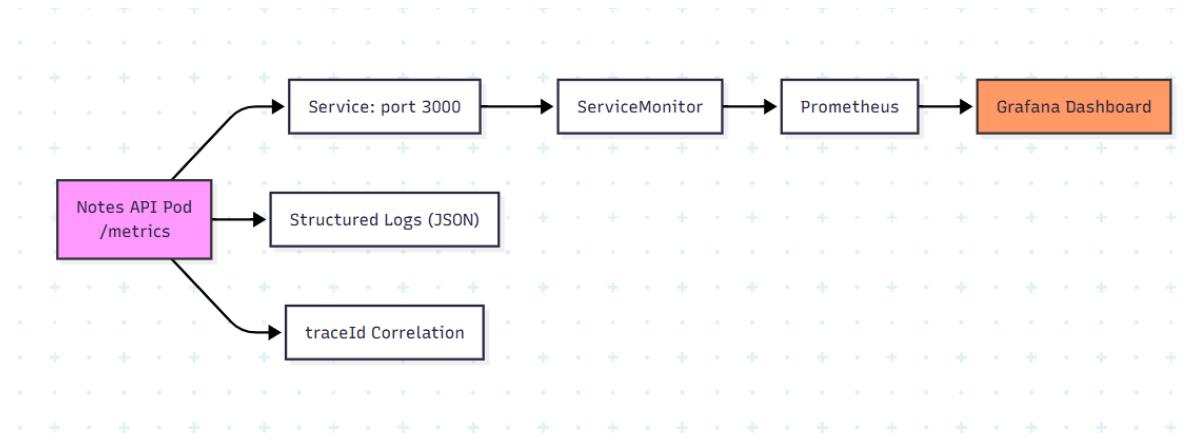

The application exposes metrics via a dedicated endpoint using the prom-client library. Collected metrics include HTTP request counts, request rates, status codes, memory usage, CPU usage, and notes count.

The screenshot shows the Prometheus UI under the 'Status > Target health' tab. There are two main sections:

- serviceMonitor/monitoring-monitoring-kube-prometheus-apiserver/0**: Shows one endpoint at <https://192.168.49.2:8443/metrics>. Labels include endpoint="https", instance="192.168.49.2:8443", job="apiserver", namespace="default", and service="kubernetes". Last scrape was 38.945s ago, and the state is UP.
- serviceMonitor/notes-api/notes-api-notes-api/0**: Shows one endpoint at <http://10.244.0.55:3000/metrics>. Labels include container="notes-api", endpoint="http", instance="10.244.0.55:3000", job="notes-api-notes-api", namespace="notes-api", pod="notes-api-notes-api-64ccdd56dd-4wqnk", and service="notes-api-notes-api". Last scrape was 22.895s ago, and the state is UP.

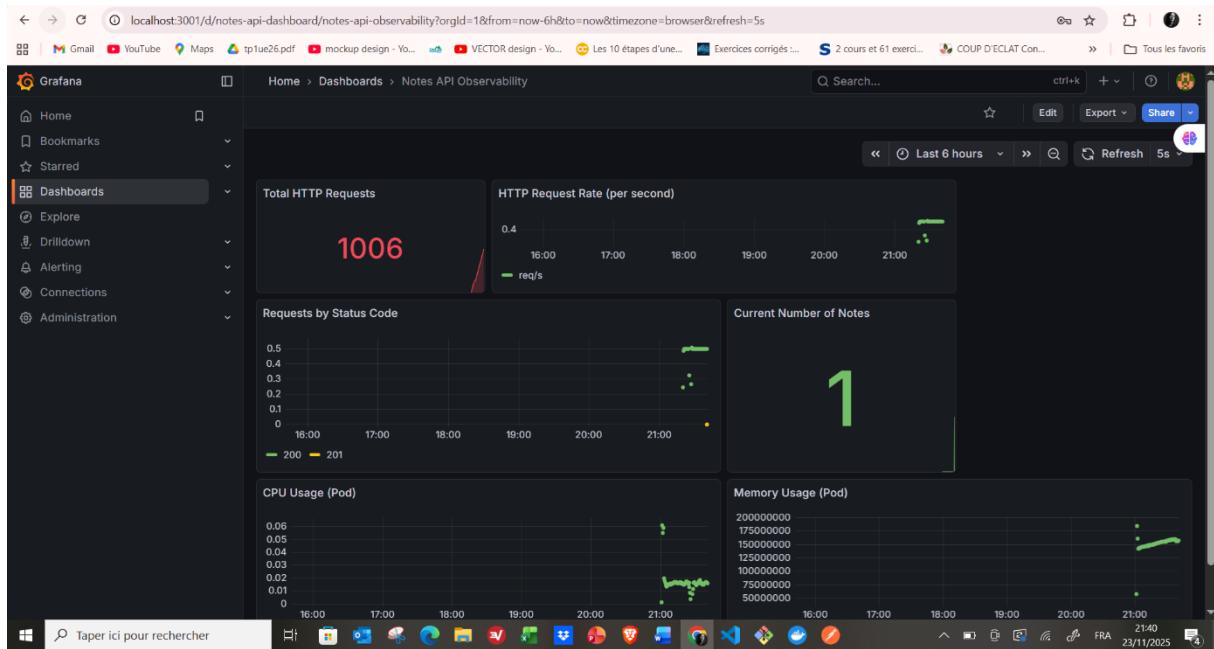

## 4.2 ServiceMonitor

A ServiceMonitor resource is deployed, allowing Prometheus to automatically discover and scrape the Notes API metrics endpoint. This integrates seamlessly with the Prometheus operator stack.

## 4.3 Grafana Dashboard

A custom Grafana dashboard visualizes key metrics including total HTTP requests, requests per second, requests by status code, number of notes, and CPU and memory usage per pod. The dashboard is configured to refresh at regular intervals.

#### 4.4 Logs, Metrics & Tracing

The application implements structured JSON logs with timestamps and trace IDs for correlation. Metrics are exposed for Prometheus collection, and lightweight request tracing is implemented using unique identifiers. This combination provides comprehensive observability.

```

PROBLÈMES 50 SORTIE CONSOLE DE DÉBOGAGE TERMINAL PORTS + ...
PS C:\Users\21658\Desktop\notes-api-devops> kubectl logs -n notes-api deploy/notes-api

PS C:\Users\21658\Desktop\notes-api-devops> kubectl exec -n notes-api -it
deploy/notes-api -- wget -qO- http://localhost:3000/health
>>
{"status": "healthy"}
PS C:\Users\21658\Desktop\notes-api-devops>

```

#### 5. Security

## 5.1 SAST – Static Application Security Testing

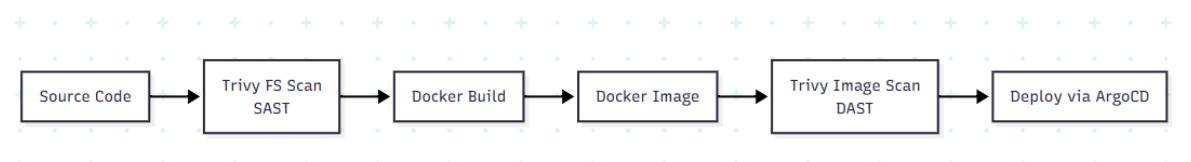

Trivy filesystem scans are executed during the CI pipeline to detect vulnerable dependencies, misconfigurations, and known CVEs in the source code before the build stage

## 5.2 DAST – Container Image Scanning

After building the Docker image, Trivy scans the final image to detect runtime vulnerabilities in the container layers and installed packages.

## 5.3 Why Security Matters

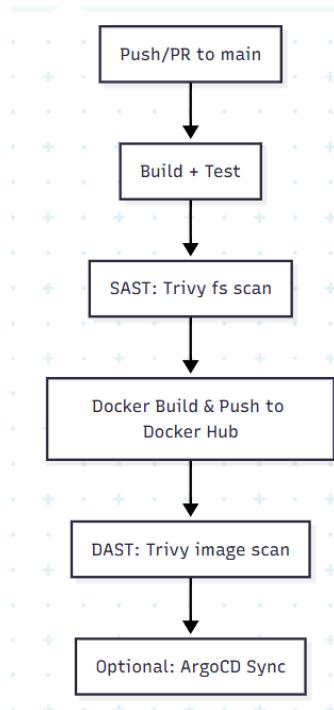

Security scanning ensures early detection of vulnerabilities, promotes secure container images, enforces compliance with DevSecOps practices, and reduces risks in production deployments.

## 6. CI/CD Pipelines

### 6.1 GitHub Actions Workflow

The pipeline includes multiple automated jobs: installing dependencies, running Jest tests, generating a coverage report, running Trivy filesystem scans, building the Docker image, pushing the image to a registry, and scanning the built image with Trivy.

## 6.2 Testing Flow

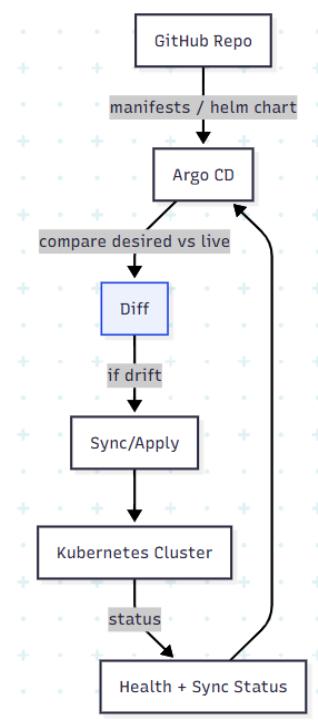

Automated tests cover the health endpoint, all CRUD operations, and metrics endpoints. The test coverage results achieved high percentages across statements, functions, and lines of code.

## 6.3 Build & Deployment Flow

The Docker image is built once and the same immutable image is promoted across environments. Argo CD automatically deploys updates to Kubernetes when a new image is available.

## 6.4 Argo CD Automation

Argo CD continuously syncs the Kubernetes cluster state with the configuration defined in the GitHub repository, enabling true GitOps deployment with automatic reconciliation.

## 7. Results

### 7.1 What Works

The application runs successfully on Kubernetes. The CI/CD pipeline is fully automated from code commit to deployment. The metrics and dashboards are operational, providing live observability. Security scans are integrated into the pipeline, and high test coverage has been achieved.

### 7.2 Deployment Evidence

Running pods are visible in the Kubernetes cluster. Argo CD shows the application as synced and healthy. Grafana dashboards display live metrics, and Prometheus is correctly scraping metrics from the application.

### 7.3 Security Results

No critical vulnerabilities are blocking deployment. Images are scanned for vulnerabilities before deployment, and secure runtime configuration is applied within the Kubernetes cluster.

## **8. Lessons Learned**

### **8.1 Real DevOps Workflow**

This project demonstrates key DevOps principles including Infrastructure as Code, GitOps practices, DevSecOps integration, and observability-driven operations in a practical implementation.

### **8.2 Common Mistakes Encountered**

During development, challenges included Ingress configuration conflicts, Service label mismatches, Prometheus scrape configuration issues, and Kubernetes context connectivity problems.

### **8.3 Improvements Made**

Issues were resolved by fixing Helm templating problems, improving security context settings, enhancing test coverage, and implementing a more structured logging format.

### **8.4 Future Improvements**

Potential future enhancements include adding distributed tracing, implementing persistent storage, adding rate limiting and authentication features, and establishing multi-environment deployment strategies for development, staging, and production.

## **9. Conclusion**

This project successfully demonstrates a complete DevOps lifecycle applied to a cloud-native application. It combines automation, security, observability, and Kubernetes best practices into a coherent, production-ready system. The project is suitable for academic submission, portfolio demonstration, DevOps interviews, and serves as a reference architecture for real-world implementations.
